

Skills, Inequality, and Referrals*

Experimental Design

Jhon Díaz[†], Manuel Munoz[‡], Ernesto Reuben^{§‡}, Reha Tuncer[¶]

December 6, 2024

1 Background and Setting

Inequality and Social Class. Colombia has consistently ranked as one of the most unequal countries in Latin America ([World Bank, 2024](#)), with the richest decile earning 50 times more than the poorest decile ([ECLAC, 2023](#)). This economic disparity is reflected by a highly stratified society, where social classes remain separated by education, family background, lifestyle, occupation, power, and geographic residence.

Stratum system. In 1994, Colombia introduced a nationwide classification system dividing the population into 6 strata based on housing characteristics and neighborhood amenities. This system, initially designed for utility subsidies from higher strata (5 and 6) to support lower strata (1 to 3), now extends to university fees and social program eligibility. While imperfect -because it disregards the income of residents, this system largely aligns with and potentially reinforces existing social class divisions ([Guevara S & Shields, 2019](#); [Uribe-Mallarino, 2008](#)). We use this exogenous cutoff as the measure

*We obtained Institutional Review Board approvals from NYU Abu Dhabi (HRPP 2024-50) and the University of Luxembourg (ERP 24-028). The study design was preregistered in the OSF Registries prior to data collection (see <https://doi.org/10.17605/OSF.IO/V9T3W>).

of social class in our experiment: Students in strata 1 to 3 are categorized as low-SES, and those in strata 4 to 6 as high-SES.

Universidad Autónoma de Bucaramanga. Our study takes place at UNAB, a medium-sized private university in Bucaramanga, Colombia, with approximately 10,000 enrolled students. UNAB’s student body is notably diverse, with slightly more than half of the students classified as low-SES (see Appendix Figure A.1 for a detailed stratum distribution). This diversity reflects the broader trend in Colombian society, where even lower middle-class families (stratum 2 and 3) prioritize university education for their children despite the financial burden (Hudson & Library of Congress, 2010, p. 103). The university environment provides a unique opportunity for collaborative inter-class contact on equal status, whose positive effects on reducing discrimination are casually documented (Lowe, 2021; Mousa, 2020; Rao, 2019). We draw our sample from a cohort of students enrolled in two semester-long courses. Each course meets weekly for three-hour sessions. Attendance is mandatory, but enforcement varies across instructors. Both courses are university-wide graduation requirements which result in large variations in academic programs and socioeconomic backgrounds across the classrooms.

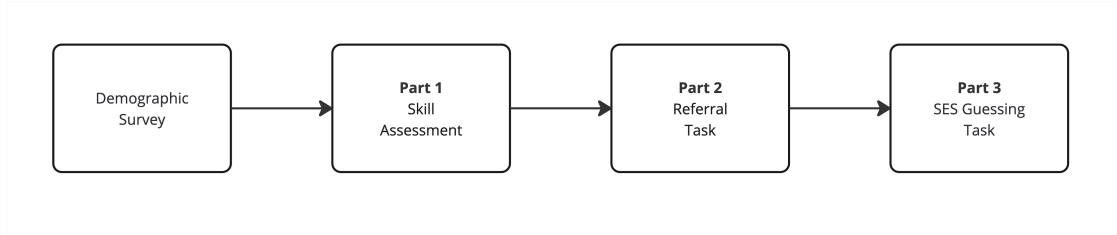

2 Design

We designed a referral experiment between students from different social classes, and experimentally varied the incentives to refer a low-SES peer. The study design consists of a single experiment with three sequential parts with sessions organized at the classroom level (see Figure 1). The instructions are provided in Appendix B.

2.1 Skill Assessment

To understand the basis for referral decisions, we collect objective measures of cognitive and social skills. These two distinct skills are crucial for the labor market and suitable

Figure 1: Experiment Timeline

Note: Participants first complete incentivized skill tests, then refer classmates for skills. In the final part, they guess the social class of their peers. This order is implemented in all sessions.

in a context with university students.¹ This approach ensures that we observe the distribution of skills in our sample, ask for referrals on these skills, and compare how well the same individuals refer peers for a specific skill. Participants perform two incentivized skill tests. They have 5 minutes to complete each test. We provide test-specific instructions and an example item before participants begin. Correctly solved items increase chances to earn a fixed bonus.²

Cognitive Skills. We use Raven’s Progressive Matrices to measure cognitive skills (Raven, 1936; Raven, Raven, & Court, 1976). Raven’s test is a well-established measure of fluid intelligence, i.e., an individual’s capacity to reason and solve problems in novel situations independent of past knowledge (Schilbach, Schofield, & Mullainathan, 2016). In this test, participants see series of images where there is a pattern with a piece that has been intentionally removed. They are tasked with choosing the piece that completes the pattern among available options. For each image, there is only one correct answer. We implement an 18-item version featuring increasingly difficult questions, with 6 response options for the first 9 items and 8 thereafter.

¹For the relationship between wages and social skills conditional on cognitive skills, see Deming (2017); Edin, Fredriksson, Nybom, and Öckert (2022); Kuhn and Weinberger (2005); Weinberger (2014).

²The tests are presented in a randomized order. No performance feedback is provided. Participants see one item at a time and cannot return to previous screens once they start a test. They are not required to answer items and can skip them if they choose to do so. We elicit beliefs about performance after each test.

Social Skills. We measure social skills with the Multiracial Reading the Mind in the Eyes Test (MRMET) from Kim et al. (2022).³ The test is an established measure for the ability to recognize emotions in others, and it has been previously used in economic experiments (van Leeuwen et al., 2018; Weidmann & Deming, 2021). MRMET consists of photos of human faces portraying different emotions, cropped so that only the eye region is visible. Participants must choose the emotion that best describes the photo from the available answers. For each photo, there is only one correct answer and 4 response options. We administer the first 36 items in MRMET.

2.2 Referral Task

We create a referral task to measure bias against low-SES peers. For each skill, participants make incentivized referrals by nominating classmates. We first explain the measured skill accompanied by an example test item. On the following page, we provide an alphabetically ordered list of all classmates. Participants make three referral choices per skill. They are instructed to exclude themselves from referrals. A classmate may be nominated once per triad. The order in which participants refer for a skill test is randomized. We incentivize referrals with classroom-level performance rankings. The three highest-scoring classmates are designated as the top 3 for a skill. Referrers are eligible for a fixed bonus for referrals among the top 3.⁴

Treatment. We have one between subject treatment, and it varies the top 3 selection. In the **Baseline** treatment, the top 3 selection is based solely on performance ranking, regardless of other participant characteristics. The **Quota** treatment modifies the top 3 selection to prioritize low-SES individuals. We reserve the first spot in the top 3 for the highest-scoring low-SES classmate, and assign the remaining two places based on performance. This guarantees at least one low-SES participant in the top 3 per skill.

³We choose MRMET because it is a race- and gender-inclusive test suitable for application in non-WEIRD (Western, Educated, Industrial, Rich, Democratic) populations like the one we sample from. The test is based on the original RMET (Baron-Cohen, Wheelwright, Hill, Raste, & Plumb, 2001).

⁴We solve ties among the top 3 randomly. We describe only the top 3 selection mechanism and provide no feedback about the top 3 composition to participants.

Participants are informed about the top 3 selection mechanism before making referral choices (Appendix Figure A.6 provides illustrations explaining the treatments). Assignment to the treatment is at the individual level within each classroom. This allows comparing the effect of the treatment while keeping the referral choice set constant.

2.3 SES Guessing Task

Participants make guesses about the anticipated SES of their classmates. We inform participants that a computer algorithm randomly selects three students belonging to strata 1, 2, or 3. They are tasked with nominating the people they believe the computer could choose at random (Appendix Figure A.7 provides the illustration explaining the task). Participants select three classmates from an alphabetically ordered list containing all their classmates. This task measures the ability to distinguish-SES independent of test performance, as SES identification is relevant to our study.

3 Sample, Incentives, and Procedure

Sample. We invited 849 UNAB undergraduate students to participate in the experiment. Our final sample consists of 713 individuals who completed the study protocol, resulting in an 83% participation rate. Table 1 presents key demographic characteristics and academic performance indicators across treatments (Appendix Table A.1 compares the sample and missing students). The sample is well-balanced between the Baseline and Quota conditions. We observe no statistically significant differences in any of the reported variables (all p values > 0.1), indicating balanced randomization. The sample is characterized by a majority of low-SES students. About one-third of the sample are first-generation college students. The gender distribution is balanced. The mean GPA of 3.95 is consistent across both treatments.

Incentives. Participants could earn bonuses worth 100,000 Pesos (about 26 US Dollars) in each part of the experiment. In the first part, we incentivized performance in the skill tests. 20% of participants were eligible for the bonus. We randomly picked one skill test

for each eligible participant and drew a number between 1 and 100. The participant received the bonus if the percentage of correct answers in the selected test exceeded the drawn number. Chances of earning the bonus increased with each correctly solved question by 5.5% ($=1/18$) for the Cognitive Skill test and by 2.78% ($=1/36$) for the Social Skill test. In the second part, we incentivized referrals among the top 3 performers. 40% of participants were eligible for the bonus. We randomly selected one skill test and one referral for each eligible participant. The participant received the bonus if their referral was among the top 3. In the third part, we incentivized the correct identification of low-SES classmates. 20% of participants in each classroom were eligible for the bonus. We randomly selected one guess for each eligible participant. The participant received the bonus if their guess correctly identified a low-SES classmate.

Procedure. Data collection occurred during the last weeks of April 2024. Our local partner, the Social Bee Lab, coordinated scheduled classroom visits and recruited research assistants to administer the experiment. Students present in class on the scheduled visit dates participated. Each classroom visit constituted a separate session. There were in total 35 sessions. Participants accessed the Qualtrics-based experiment using their smartphones during these visits. The median time to complete the survey was 20 minutes, with a compensation of \$26 for 117 lottery winners.

Table 1: Comparison of demographic characteristics and academic outcomes across treatment conditions

	Baseline	Quota	<i>p</i>
Low-SES	59%	55%	0.297
Cognitive skill (out of 18)	10.04	10.27	0.322
Social skill (out of 36)	18.45	18.50	0.886
GPA	3.95	3.95	0.828
Entry Exam	61.85	62.17	0.638
Age	19.33	19.02	0.228
Female	52%	47%	0.195
First Generation	34%	37%	0.386
Ethnic Minority	1%	3%	0.133
Rural Community	30%	27%	0.308
Has Scholarship	1%	1%	0.916
# Semesters at UNAB	3.18	3.17	0.916

Note: Low-SES, female, first generation, ethnic minority, rural, and has scholarship represent binary outcomes and *p*-values for these variables are from two-sample tests of proportions. For continuous variables (age, GPA, cognitive skill, social skill, entry exam, and semester), *p*-values are from two-sample t-tests with equal variances. All reported *p*-values are two-tailed. Sample sizes vary slightly across measures due to missing data.

4 Empirical Analysis

Can peers identify skills?

Our first goal is understanding whether higher skilled individuals get more referrals. Because every referrer nominates 3 classmates per skill, analyzing only the extensive margin, i.e., whether an individual gets a referral, is not very informative.⁵ We consider the percentage share of referrals from individuals in Baseline condition as our dependent variable. This approach combines the intensive and extensive margins and also makes comparisons across classrooms with different sizes easier.⁶ Formally, we define the percentage share of referrals received by individual i from participants in classroom c and in Baseline condition ($\forall j \in B_c$) for skill $s \in \{Cognitive, Social\}$ as:

$$y_{ic}^s = \frac{\sum_{j \neq i} r_{ijc}^s}{n_c - \mathbb{1}(i \in B_c)} \times 100 \quad (1)$$

where n_c represents the number of participants in the Baseline condition in classroom c . The indicator r_{ijc}^s takes value 1 if participant j in the Baseline condition refers individual i for skill s , and 0 otherwise, requiring both i and j to be in the same classroom c . The denominator $n_c - \mathbb{1}(i \in B_c)$ accounts for the maximum possible referrals that individual i could receive. If i is in the Baseline condition ($\mathbb{1}(i \in B_c) = 1$), we subtract one from n_c to account for the self-referral restriction.⁷ This normalized measure represents the percentage of potential referrals actually received by each individual, adjusting for classroom size and treatment status. By construction, $y_i^s \in [0, 100]$ for all c , and we can compare referrals across classrooms of different sizes. Appendix Figure

⁵Only 86 of the 849 students (10%) never get a referral for either skill.

⁶The number of participants in a classroom mechanically drives the number of total referrals that could be received by an individual. By normalizing referrals we focus on differences within classrooms.

⁷We find that 33.8 percent of participants in the sample for cognitive and social skills self-referred, while explicitly instructed not to do so. In Appendix Table A.5 we compare the outcomes of the subsample who self-refer. Those who self-refer are 10 percent more likely to be low-SES, and have systematically lower cognitive skills (0.2 SD) and GPA (0.25 SD). As self-referrers are not informative and add noise to our estimates, we drop these instances from our paired referral-referrer sample in subsequent analyses. Self-referring participants' remaining referral choices are kept in the dataset.

A.3 presents the distribution of our dependent variables and illustrates with an example. Under performance pay, higher performing classmates in skill tests should collect more referrals if classmates can successfully identify skills. Our only independent variables are standardized skill test scores. We estimate referral percentage shares y_i^s :

$$y_i^s = \beta_0^s + \beta_1^s Skill_i^s + \epsilon_i^s \quad (2)$$

Table 2 illustrates our first findings. The comparison of interest is the point estimates for different skills. In column (1), a one standard deviation increase in cognitive skill causes a 1.2 percentage point increase in the share of referrals received. On a base rate of 13%, this is a modest increase of 9 percent. In column (2), 95% confidence intervals rule out that a one standard deviation increase in the social skill result in more than a 1 percentage point difference in the share of referrals received. Participants have difficulties identifying skills in the Baseline condition, with modest recognition of cognitive and no recognition at all of social skills.

Table 2: Share of referrals conditional on skill

	(1)	(2)
	Cognitive	Social
Skill	1.197** (0.479)	0.037 (0.510)
Constant	12.986*** (0.653)	13.049*** (0.521)
Observations	665	665

Note: Classroom-level clustered standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Dependent variables are the percentage of referrals received relative to all referrals. “Skill” refers to standardized test scores for cognitive and social skills. Sample restricted 665 individuals for whom we have complete administrative and experimental data.

In the absence of a clean skill-signal from their peers, participants may have referred

classmates using proxies of skills. We define proxies as peer beliefs about strong correlates for skills. The most straightforward proxy for cognitive skills would be the “good students” in the classroom, as measured by GPA. However, as [Heckman and Kautz \(2012\)](#) show, cognitive skills and grades are far from perfectly correlated and such beliefs may not be accurate. Indeed, in our sample, GPA correlates very weakly with skills (see Appendix Table [A.3](#)). We attempt to capture these beliefs by including standardized GPA scores as an independent variable in Equation (2) and re-estimate referral percentage shares y_i^s .

Table 3 illustrates our findings. The comparison of interest is the difference between point estimates for skills and GPA. In column (1), a one standard deviation increase in cognitive skill causes a 0.9 percentage point increase in the share of referrals received when controlling for GPA. On a base rate of 12.8%, this is a comparable increase in magnitude of about 7 percent to our previous estimate in Table 2, and suggests cognitive skills have an independent direct effect for referrals. However, a one standard deviation increase in GPA causes a substantial 3.9 percentage point increase in the share of referrals received when controlling for cognitive skill. This is an increase of more than four times in terms of magnitude (30 percent) when compared to cognitive skill, and suggestive of the weight put in GPA in referrals. In column (2), 95% confidence intervals rule out that a one standard deviation increase in the social skill result in more than a 1 percentage point difference in the share of referrals received. This finding is consistent with our previous estimate where participants cannot identify social skills. On the other hand, a one standard deviation increase in GPA causes a substantial 3.4 percentage point increase in the share of referrals received when controlling for social skill. This is a similar albeit slightly smaller increase of 26 percent in the share of referrals for social skill. For both skills, we find strong evidence for the GPA proxy for referral decisions. In the subsequent section we expand more on how referral decisions are made.

Table 3: Share of referrals conditional on skill and academic performance

	(1)	(2)
	Cognitive	Social
Skill	0.873*	-0.278
	(0.467)	(0.460)
GPA	3.949***	3.429***
	(0.664)	(0.581)
Constant	12.806***	12.891***
	(0.662)	(0.636)
Observations	665	665

Note: Classroom-level clustered standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Dependent variables are the percentage of referrals received relative to all referrals. “Skill” refers to standardized test scores for cognitive and social skills. GPA is standardized to mean zero and unit variance.

Overlapping referrals

Diversity in referral choices vary substantially between participants as they nominate 3 individuals per skill and can make overlapping referrals across skills. In Appendix Figures A.4a and A.4b, we show that only 20.5 percent of participants pick all unique classmates for their 6 choices. In fact, depending on our measures, between 50 to 70 percent of participants make 2 or 3 overlapping referrals and the diversity in referral choices is much lower than what we anticipated.⁸

With such a large share overlapping referral choices, participants could hold beliefs that classmates who with higher scores in one skill could also have higher scores in the other skill. Would such beliefs be accurate? There is only modest ($\rho = 0.267$) correlation between the two skills (see Appendix Table A.3). To understand whether

⁸In Appendix Table A.6 we compare the characteristics of referrers make unique referrals to the remainder of the sample. The results suggest minimal differences in GPA and skills.

making overlapping referrals is strategic, we turn to the incentives. Participants were incentivized to pick the top 3 performers in their classroom for each skill to earn a fixed bonus. Looking at the characteristics of top skilled participants in Appendix Table A.7, we find that conditional on being among the top 3 for one of the skills, only 1 in 3 participants were in the top 3 for both skills. This suggests making more than 1 overlapping referral choice would decrease the chances to win the bonus.

Coupled with the notable difficulties in identifying skills documented in the previous section, a competing explanation for the amount of overlapping referral choices would be that individuals who refer classmates twice for both skills are worse at observing skills. This would imply underlying heterogeneity in skill identification resulting in different referral strategies. We can test these competing hypotheses in our data: If “twice” referrers -defined as those who refer an individual for both skills- are better at identifying at least one of the skills, this would give more credence to beliefs about correlated skills. On the other hand, if “twice” referrers are worse in skill identification compared to single-referrers or use GPA proxy for referrals, it would imply that they have no information about skills. We compare peers who receive referrals twice from their classmates to those who receive referrals only once per skill. Formally, let indicator r_{ijc}^{twice} take value 1 if individual j referred individual i for both skills. The percentage share of referrals received by individual i from participants in classroom c and in Baseline condition ($\forall j \in B_c$) is:

$$y_{ic}^{twice} = \frac{\sum_{j \neq i} r_{ijc}^{twice}}{n_c - \mathbb{1}(i \in B_c)} \times 100 \quad (3)$$

where n_c represents the number of participants in the Baseline condition in classroom c . The indicator r_{ijc}^{twice} takes value 0 if participant j in the Baseline condition does not refer individual i for both skills. The denominator $n_c - \mathbb{1}(i \in B_c)$ accounts for the maximum possible “twice” referrals that individual i could receive. If i is in the Baseline condition ($\mathbb{1}(i \in B_c) = 1$), we subtract one from n_c to account for the self-referral restriction as before. Similarly, let $r_{ijc}^{s,single}$ take value 1 if individual j referred individual i only for skill s . The percentage share of “single” referrals received by individual i from

participants in classroom c and in Baseline condition ($\forall j \in B_c$) for skill s is:

$$y_{ic}^{s,single} = \frac{\sum_{j \neq i} r_{ijc}^{s,single}}{n_c - \mathbb{1}(i \in B_c)} \times 100 \quad (4)$$

and it follows trivially that for any s , percentage share of “single” and “twice” referrals received by individual i from participants in classroom c and in Baseline condition ($\forall j \in B_c$) must add up to the total share of referrals received:

$$y_{ic}^s = y_{ic}^{s,single} + y_{ic}^{twice} \quad (5)$$

we regress Equation 2 supplanted with GPA for our three new dependent variables and report our findings in 4.

Table 4: “Twice” versus “single” referral share conditional on skills and academic performance

	(1)	(2)	(3)
	Twice	Cognitive Only	Social Only
GPA	3.172*** (0.464)	0.801** (0.391)	0.260 (0.334)
Cognitive Skill	-0.042 (0.416)	1.006*** (0.270)	
Social Skill	-0.353 (0.304)		0.086 (0.381)
Constant	7.407*** (0.524)	5.400*** (0.386)	5.485*** (0.376)
Observations	665	665	665

Note: Classroom-level clustered standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variable in column (1) is the percentage of “double” referrals received from the same referrer, in column (2) for cognitive skill only, and in column (3) for social skill only. Cognitive and social skills are the respective standardized test scores. GPA is standardized to mean zero and unit variance.

Social Class and Quota

In the following empirical specification, we document whether Quota treatment causes referral shares to increase compared to the Baseline. We consider the percentage share of referrals received by total number of referrals that could have been received for both skills, disaggregated by referrer’s treatment as our dependent variable (see Appendix Figure A.2 for its distribution and construction). The reason for grouping over skills is because skill referrals are very similar. Decomposing by treatment allows comparing the effect of treatments, controlling for classroom SES composition. By design, we randomize participants in each classroom into treatments balancing for gender and SES.

In the Quota treatment, the incentive to refer low-SES should increase referrals to low-SES classmates. We therefore include referral SES as an independent variable, in addition to GPA and individual controls in $\mathbf{X}_i$.⁹ We estimate referral percentage y_i :

$$y_i = \beta_0 + \beta_1 GPA_i + \beta_2 SES_i + \mathbf{X}_i\gamma + \epsilon_i \quad (6)$$

Table ?? illustrates our findings. Our comparison of interest is estimates across treatments. In columns (1) and (2), we find no statistically significant evidence of a bias against low-SES in the Baseline treatment when referrals are aggregated by social class. The point estimates have a negative sign in both main and classroom fixed effects specifications and suggest a marginal but insignificant tendency to refer high-SES classmates. The 95% confidence intervals rule out that being low-SES causes more than a 1.5 percentage point difference in the percentage share of referrals received. In columns (3) and (4), we consider the percentage share of referrals made by referrers in the Quota treatment. We find larger point estimates in absolute terms for the low-SES dummy in comparison to the Baseline treatment. They suggest a stronger but still insignificant tendency to refer high-SES classmates. The 95% confidence intervals rule out that being low-SES causes more than a 2 percentage point difference in the percentage share of

⁹The relationship between social class and referrals may operate through other channels than socioeconomic status, for example being a first-generation college student, having rural background, etc., which correlate strongly with low-SES. We focus on the effect of social class through-SES only.

referrals received. Contrary to our hypothesis, we can rule out that the Quota treatment causes a meaningful increase in the referrals received by low-SES classmates when controlling for GPA and classroom SES composition. In the next section we expand on this finding by decomposing referrals further by SES of the referrer. This will help us identify whether the negative sign on the low-SES dummy is driven by a particular social class.

We obtain the largest point estimates for GPA in column (1) and (2), documenting the pure effect of performance-pay incentives in the Baseline treatment without considerations of social class. A one standard deviation increase in GPA increases the percentage share referrals received from participants in the Baseline condition by 3.8 percentage points on a base rate of 12.7%, a 30 percent increase. In column (2), we add classroom fixed effects, and GPA point estimates become 4 percentage points. The overall effect on referral share of the GPA estimates are almost equal in column (2). A one standard deviation increase in GPA increases the percentage share of referrals by 31 percent. We now compare the sizes of the GPA point estimates to those for the Quota treatment found in columns (3) and (4). In column (3), a one standard deviation increase in GPA increases the percentage share referrals received from participants by 2.5 percentage points on a base rate of 13.6%, a modest 18 percent increase. When adding classroom fixed effects in column (4), a one standard deviation increase in GPA increases the percentage share referrals received from participants by 2.6 percentage points on a base rate of 13.6%, a comparable 19 percent increase. We find consistently that GPA point estimates become smaller with the introduction of low-SES referral incentives, suggesting performance considerations get confounded in the Quota treatment.

Table 5: Treatment effect on SES controlling for performance

	(1)	(2)
	Cognitive	Social
Quota	-0.073 (0.755)	0.299 (0.716)
Low SES	-1.230 (1.079)	0.364 (1.282)
Quota $\times$ Low-SES	-0.167 (1.117)	-0.835 (1.181)
Skill	0.594 (0.448)	0.201 (0.426)
GPA	3.184*** (0.517)	2.819*** (0.493)
Constant	13.551*** (0.986)	12.706*** (0.952)
Observations	1,330	1,330

Note: Classroom-level clusted standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variables are the percentage of referrals received for cognitive and social skills. Quota is a dummy for referrals received from classmates in the quota condition. Low-SES is a dummy for participant's socioeconomic status. Skill refers to standardized Raven's test score for cognitive referrals (column 1) and Reading the Mind in the Eyes test score for social referrals (column 2). GPA is standardized to mean zero and unit variance.

Table 6: Treatment effects on referrals with skill and academic performance interactions

	(1) Cognitive	(2) Social
Quota	-0.091 (0.302)	-0.131 (0.225)
Skill	0.873* (0.467)	-0.278 (0.460)
Quota $\times$ Skill	-0.380 (0.697)	0.966* (0.561)
GPA	3.949*** (0.664)	3.429*** (0.581)
Quota $\times$ GPA	-1.524** (0.697)	-1.221* (0.678)
Constant	12.806*** (0.662)	12.891*** (0.636)
Observations	1,330	1,330

Note: Classroom-level clustered standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variables are the percentage of referrals received for cognitive and social skills. Treatment is an indicator for the quota condition. "Skill" refers to standardized Raven's test score in column (1) and Reading the Mind in the Eyes test score in column (2). All continuous variables (skills and GPA) are standardized (mean zero, unit variance). The treatment interactions capture differential effects of the quota condition by skill level and academic performance.

Table 7: Treatment effects on referrals by referrer socioeconomic status

	High-SES Referrers		Low-SES Referrers	
	Cognitive	Social	Cognitive	Social
Quota	0.509 (0.548)	0.387 (0.502)	-0.274 (0.449)	-0.300 (0.414)
Skill	0.761 (0.693)	-0.342 (0.711)	1.294* (0.690)	-0.110 (0.512)
Quota $\times$ Skill	-0.512 (1.119)	0.414 (0.833)	-0.108 (0.829)	1.578** (0.637)

Quota $\times$ GPA	-1.630 (1.029)	-2.131** (0.967)	-1.392 (1.054)	-0.527 (0.887)
Constant	12.266*** (0.620)	12.197*** (0.591)	12.999*** (0.728)	13.164*** (0.709)
Observations	1,319	1,319	1,328	1,328

Note: Standard errors clustered at classroom level in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variables are the percentage of referrals received for cognitive and social skills. Treatment is an indicator for the quota condition. "Skill" refers to standardized Raven's test score for cognitive referrals and Reading the Mind in the Eyes test score for social referrals. All continuous variables (skills and GPA) are standardized (mean zero, unit variance). High-SES and Low-SES indicate the socioeconomic status of the referrer.

4.1 Social Class Homophily

In this section, we document social class homophily between high-SES classmates.¹⁰ Our dependent variable is the percentage share of referrals received by total number of referrals as specified before, but now further decomposed by the social class of referrers (see Appendix Figure ?? for the distribution of referrals across SES). This approach allows us to maintain control for classroom SES composition, performance, and treatment status. We begin our analysis with the share of referrals coming from high-SES, then present the equivalent analysis for low-SES referrers. We estimate percentage share of referrals, y_i , the same way in Equation 6.

Table 8 presents our analysis of referrals from high-SES classmates across treatments. In columns (1) and (2) for the Baseline treatment, we find that GPA strongly predicts referrals from high-SES peers. A one standard deviation increase in GPA raises the percentage share of referrals by approximately 3.2 percentage points, representing a 27% increase from the baseline mean. This effect remains stable when including classroom fixed effects in column (2). The coefficient on Low-SES dummy is statistically insignificant and small in magnitude, suggesting no substantial bias in referral from high-SES peers in the Baseline treatment. In columns (3) and (4) for the Quota treatment, we observe three notable changes: First, the GPA point estimates become substantially smaller, to around 1.8 percentage points, and are only marginally significant. Second, the Low-SES dummy becomes larger in magnitude, -3.8 percentage points, and statistically significant. This is a substantial 25% decrease, of the same magnitude as the effect of GPA with pure-performance incentives in the Baseline. Third, variance explained by the model drops and standard errors increase, indicating the increased noise for the referral decisions. These suggest that the Quota treatment, had the opposite effect for high-SES referrers and decreased the referrals made for their low-SES classmates. This finding is contrary to the Quota treatment’s intended effect of increasing low-SES

¹⁰See McPherson, Smith-Lovin, and Cook (2001) for a discussion on homophily in general, for evidence on social class homophily see Chetty et al. (2022a, 2022b). For experimental evidence on a different type of homophily (gender) in referrals see Beaman, Keleher, and Magruder (2018).

referrals, and is robust to performance and classroom SES composition.

Table 8: Percentage share of referrals from high-SES, decomposed by treatment

	(1)	(2)	(3)	(4)
Dep. Var	High-SES in Baseline		High-SES in Quota	
GPA	3.230*** (0.730)	3.265*** (0.772)	1.742* (0.776)	1.916* (0.849)
Low-SES	-1.142 (1.282)	0.054 (1.291)	-3.836** (1.477)	-3.440* (1.592)
Constant	12.085*** (1.076)	11.798*** (1.085)	15.390*** (1.342)	15.427*** (1.518)
Individual controls	Yes	Yes	Yes	Yes
Classroom FE	No	Yes	No	Yes
Observations	665	665	665	665
R-squared	0.052	0.125	0.035	0.081

Note: Robust standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variable is the percentage of referrals from high-SES classmates. Columns (1) and (2) show results for the Baseline treatment, columns (3) and (4) for the Quota treatment. Individual controls include age, gender, semester, and share of same study program. Sample restricted to participants with complete administrative and experimental data.

Table 9 presents our analysis of referrals from low-SES classmates across treatments. In columns (1) and (2) for the Baseline treatment, we find that GPA strongly predicts referrals from low-SES peers. A one standard deviation increase in GPA raises the percentage share of referrals by approximately 3.9 percentage points, representing a 31% increase. This effect remains stable when including classroom fixed effects in column (2). The coefficient on Low-SES dummy is statistically insignificant and small in magnitude (0.06-0.37 percentage points), suggesting no homophily in low-SES referrals in the

Baseline treatment. In columns (3) and (4) for the Quota treatment, we observe once again that GPA point estimates become smaller, to around 2.8 percentage points, though they remain highly significant. The Low-SES dummy also becomes larger in magnitude (0.82-0.91 percentage points), indicating that referrals did increase for other low-SES, but point estimates remain statistically insignificant. The variance explained by the model drops again, indicating the noise in the referral decisions. Comparing these to referrals from high-SES participants in Table 8, we find that while both groups strongly refer based on GPA in the Baseline treatment, low-SES show no significant in-group bias, unlike high-SES that exhibit significant in-group bias in the Quota treatment. As documented by the larger GPA point estimates, low-SES sensitivity to performance is always higher. The Quota treatment decreases sensitivity for performance both low and high-SES, but by different rates: Increase in referral share by a one standard deviation increase in GPA for low-SES across treatments goes down from $\frac{4.26}{12.56} \approx 34\%$ to $\frac{2.82}{11.64} \approx 24\%$, a decline of 29 percent. This is in contrast to a sharper decline of 57 percent by $\frac{3.27}{11.80} \approx 28\%$ to $\frac{1.92}{15.43} \approx 12\%$ from column (2) to (4) in Table 8 for high-SES referrers. This asymmetry can be indicative of high-SES struggling to identify high performing low-SES peers, or just having trouble identifying low-SES. We substantiate this claim by looking at how well high-SES can identify low-SES, in Appendix Figure ??.

Table 9: Percentage share of referrals from low-SES, decomposed by treatment

	(1)	(2)	(3)	(4)
Dep. Var	Low-SES in Baseline		Low-SES in Quota	
GPA	3.949*** (0.616)	4.258*** (0.665)	2.766*** (0.693)	2.821*** (0.737)
Low-SES	0.064 (1.182)	0.371 (1.211)	0.817 (1.294)	0.910 (1.293)
Constant	12.450*** (1.092)	12.560*** (1.089)	11.492*** (1.176)	11.644*** (1.179)
Individual controls	Yes	Yes	Yes	Yes
Classroom FE	No	Yes	No	Yes
Observations	665	665	665	665
R-squared	0.078	0.158	0.039	0.119

Note: Robust standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variable is the percentage of referrals from low-SES classmates. Columns (1) and (2) show results for the Baseline treatment, columns (3) and (4) for the Quota treatment. Individual controls include age, gender, semester, and share of same study program. Sample restricted to participants with complete administrative and experimental data.

A Additional Figures and Tables

A.1 Additional Figures

Figure A.1: Stratum distribution of the sample

Figure A.2: Referrals by treatment

Note: The figure shows the percentage share of referrals received for skills, disaggregated by Baseline and Quota treatments. This variable is calculated as the number of actual referrals received divided by the maximum possible referrals a student could have received. To illustrate: Consider a classroom with 25 students where 20 participated in the experiment, with 10 per treatment. A student could receive a maximum of 18 referrals from others in the same treatment (1 referral per skill minus 2 referrals made by student if they participated), and 20 referrals from the remaining treatment. We normalize the total referrals received in each treatment by this maximum possible number to obtain the percentage share shown in the figure. The distribution of referrals is right-skewed with extreme outliers. There is little difference between referrals between Baseline and Quota treatments: Both have means around 11.5% with medians 8.8% and 9.1% respectively. A notable feature is the high concentration of students receiving no referrals, particularly in the Quota treatment where the 25th percentile is zero (compared to 3.3% in Baseline). The majority of students (75th percentile) in both treatments receive fewer than 17% of possible referrals, though the distributions have heavy right tails with some students receiving up to 80% of possible referrals.

Figure A.3: Referrals in Baseline

Note: The figure shows the percentage share of referrals received across cognitive and social skills from participants in Baseline condition. It is calculated as the number of actual referrals received divided by the maximum possible referrals a student could have received. To illustrate: Consider a classroom with 25 students with 20 participants, and assume 10 participants in each condition. In this classroom, an individual could receive maximum 10 referrals for a skill from classmates in Baseline condition. This number is 9 if the individual is also in Baseline (exclude 1 self-referral possibility). We normalize the referrals received by the maximum to obtain the percentage share shown in the figure. The distribution of referrals is right-skewed with extreme outliers, with consistency across cognitive and social skills.

Note: Figure (a) shows the distribution of overlapping referrals across treatments, and excludes self-referrals. Figure (b) shows the distribution of overlapping referrals with and without self-referrals. The first bar (value of 0) always indicates the share of participants with 6 unique referrals. The last bar (value of 3) always indicates the share of participants with 3 identical referral choices. We find that treatments do not change referral dispersion, but excluding self-referrals significantly underestimates the share of participants who have 3 identical referral choices. In their original referral choices, about 70 percent of our sample had at least 2 common referrals.

Figure A.5: Distribution of standardized GPA across SES

Note: There are no significant differences in standardized GPA scores between high-SES ($M = 0.058$, $SD = 1.032$, $n = 286$) and low-SES participants ($M = 0.033$, $SD = 0.970$, $n = 382$), $t(666) = 0.32$, $p = 0.746$, $d = 0.025$.

A.2 Additional Tables

Table A.1: Comparison of Variables Between the Sample and Missing Students

	Sample	Missing	<i>p</i>
Referral share (both skills)	0.127	0.043	0.000
GPA (standardized)	0.044	-0.273	0.001
Entry Exam (standardized)	0.028	-0.168	0.046
# Semesters at UNAB	3.171	3.188	0.884
Age	19.182	20.287	0.001
Female	49.8%	48.5%	0.788
Ethnic Minority	2.1%	4.4%	0.114
Rural Community	28.8%	31.6%	0.501
Has Scholarship	0.8%	0.7%	0.899

Note: Values for female, ethnic minority, rural community, and scholarship represent percentages. All other variables represent means. *p*-values for gender, ethnic, rural, and scholarship are from two-sample tests of proportions. For all other variables, *p*-values are from two-sample t-tests with equal variances. All tests compare the sample and missing students. All reported *p*-values are two-tailed.

Table A.2: Percentage of referrals across specifications conditional on performance

	(1)	(2)	(3)	(4)
Dep. Var.	All	Baseline	Quota	All
GPA	3.031*** (0.418)	3.765*** (0.515)	2.402*** (0.513)	3.306*** (0.529)
Cognitive	0.243 (0.437)	0.278 (0.491)	0.277 (0.545)	0.327 (0.455)
Social	0.412 (0.370)	0.114 (0.426)	0.577 (0.511)	0.159 (0.302)
Constant	14.873*** (2.358)	15.598*** (3.091)	14.042*** (2.952)	14.421*** (2.324)
Classroom FE	No	No	No	Yes
Individual Controls	Yes	Yes	Yes	Yes
Observations	665	665	665	665
R-squared	0.112	0.118	0.047	0.115

Note: Robust standard errors in parentheses. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. The dependent variable is the percentage of referrals received relative to potential referrals. Column (1) shows results for all referrals, column (2) for baseline condition only, column (3) for quota treatment only, and column (4) includes classroom fixed effects. Controls include gender, age and semester. Sample is restricted to participants with complete administrative and experimental data. All continuous variables are standardized.

Table A.3: Correlation between GPA and skills

	GPA	Cognitive	Social
GPA	1.000		
Cognitive	0.085	1.000	
Social	0.093*	0.267*	1.000

Note: Pairwise correlation between GPA and skills. * indicates significance at the 5% level with Bonferroni correction. Sample is restricted to participants with complete administrative and experimental data.

Table A.4: Between-Classroom Variation in Program Concentration

Statistic	Most common program share
Mean	0.424
Standard Deviation	0.216
10th percentile	0.174
25th percentile	0.292
Median	0.345
75th percentile	0.533
90th percentile	0.696
# classrooms with share 1	3
Most diverse classroom	0.154
# classrooms	35

Note: Table shows the distribution of program concentration across classrooms, measured by the share of students from the most common program in each classroom. Three classrooms are completely homogeneous (share = 1). In the median classroom, the most common program accounts for 34.5% of students. The most diverse classroom has only 15.4% of students from the same program. Data based on 849 students across 35 classrooms.

Table A.5: Characteristics of self-referrers

	No self-referral	Any self-referral	Δ
GPA	0.132 (1.003)	-0.120 (0.966)	0.252
Cognitive Skills	0.087 (0.988)	-0.118 (1.023)	0.205
Social Skills	0.034 (1.003)	-0.038 (0.959)	0.072
Low-SES	0.605 (0.490)	0.511 (0.501)	0.094
N	440	225	665
Share (%)	66.2	33.8	100

Note: Table compares standardized scores between participants who self-referred at least once ($N = 225$) and those who did not ($N = 440$). Positive differences indicate higher scores for those who never self-referred. The results suggest self-referrers have systematically lower cognitive skills and GPA, consistent with the fact that we instructed explicitly against making self-referrals, and are more likely to be low-SES. Standard deviations in parentheses, samples restricted to participants with complete administrative and experimental data.

Table A.6: Characteristics of participants who make overlapping referrals

	All unique referrals	Overlapping referrals	Δ
GPA	0.057 (0.983)	0.045 (1.009)	0.012
Cognitive Skill	0.110 (1.005)	0.024 (0.979)	0.086
Social Skill	-0.014 (0.938)	0.033 (0.981)	-0.047
Low-SES	0.530 (0.501)	0.597 (0.491)	-0.067
N	132	512	644
Share (%)	20.5	79.5	100

Note: Table compares characteristics between participants who made overlapping referrals ($N = 512$, 79.5%) and those who did not ($N = 132$, 20.5%). Overlapping referrals indicate cases where a student referred the same classmate at least once for cognitive or social skills. Positive differences indicate higher scores for those who made no overlapping referrals. The results suggest minimal differences in GPA and social skills. Referrers who made no overlapping referrals have slightly higher cognitive skills and are 6.7 percent more likely to be high-SES. Standard deviations in parentheses, sample restricted to participants with complete administrative and experimental data.

Table A.7: Characteristics of Top Performers and Referrals

	Cognitive		Social		Both
	Top 3	Referrals	Top 3	Referrals	Top 3
Cognitive Skill	1.223 (0.419)	0.112 (1.009)	0.383 (0.922)	0.058 (1.015)	1.201 (0.458)
Social Skill	0.357 (0.923)	0.086 (0.996)	1.340 (0.395)	0.042 (1.009)	1.391 (0.453)
GPA	0.277 (0.990)	0.251 (1.021)	0.264 (1.046)	0.212 (1.004)	0.551 (0.897)
Low-SES	0.457 (0.500)	0.532 (0.499)	0.456 (0.500)	0.555 (0.497)	0.500 (0.507)
N	129	1,759	114	1,775	36
Share (%)	20.0	100	17.7	100	5.6

Note: Table shows characteristics of students ranked in the top 3 of their classroom and average characteristics of referred students, by skill. Standard deviations in parentheses. Sample restricted to participants with complete administrative and experimental data. All continuous variables are standardized.

B Experiment

We include the English version of the instructions used in Qualtrics. Participants saw the Spanish version. Horizontal lines indicate page breaks, and clarifying comments are inside brackets.

Please enter the password:

[classroom-specific password sent to each participant the day before data collection]

Welcome

Welcome to this study organized by the Social Bee Lab. You have been invited to participate in a survey where you can make a series of decisions. The study takes approximately 20 minutes to complete. During the study, you should not communicate with any other students. If you have any questions at any time, please raise your hand. One of the assistants will help you privately.

In this study, you can win bonus money depending on your choices. In total, we will draw [classroom-specific number equal to 40% of class size] bonuses of 100.000 pesos among the participants of this classroom. It is also possible for the same person to win more than one voucher. The following screens will detail how the bonus draw will be conducted. The UNAB finance office will make the payment of the vouchers through Nequi.

All your decisions in this survey will be anonymized. Therefore, the answers you provide will not affect your grades in this class or your records at the university. We will use your personal information to determine the bonus allocation, but after that, we will remove any data that identifies you.

This survey has several parts. Each of these parts has specific instructions. Please read the instructions for each part carefully because they describe how you can earn bonuses. This study has been approved by the [omitted for anonymous review] on the condition that all the information we provide is true and all the bonuses we offer are real. On the next screen, we present you with an informed consent form that you must accept to participate in this study.

Informed Consent

You have been invited to participate in a study to learn more about how people make decisions in common scenarios.

This study is conducted by [omitted for anonymous review] and the Social Bee Lab at UNAB. The purpose of this study is to broaden our understanding of how people make decisions.

Participation in this study is voluntary. You may opt-out at any time. No known risks are associated with your participation in this project beyond those of everyday life. Apart from the monetary bonuses that will be drawn, participation has no direct benefits.

The Social Bee Lab is in charge of data collection. Your answers in this study are anonymous and will not be shared with anyone. In addition to your answers, UNAB will provide the Social Bee Lab with administrative records of your courses and your university entrance exam score. Your records, decisions, and your identity will be kept strictly confidential. Data about you collected within the scope of the study are used for scientific purposes only and are treated as strictly confidential. The Social Bee Lab will anonymize your data, and the researcher will analyze it without knowing your identity. All data generated will be stored on the researcher's computer. You have the right to access your personal data and request its deletion. You can exercise this right by contacting the researcher.

If something is unclear or you have any questions, you can contact [omitted for anonymous review].

If you have questions about your rights as a participant, you can contact [omitted for anonymous review].

By continuing to the next screen, you agree to participate in this study.

Before you start, please answer these four questions.

What is your gender?

[Male, Female]

What is the socio-economic stratum to which your family belongs?

[Stratum 1 to Stratum 6]

What is your father's highest acquired level of education?

[Primary school, High school, Technical school, Undergraduate, Graduate, Postgraduate, Not applicable.]

What is your mother's highest acquired level of education?

[Primary school, High school, Technical school, Undergraduate, Graduate, Postgraduate, Not applicable.]

Part 1

You will now participate in two quizzes, each lasting five minutes. Please try to answer

them to the best of your ability.

We will allocate up to [classroom-specific number equal to 20% of class size] bonuses of 100.000 pesos in this first part. The steps to allocate the bonuses for Part 1 are explained below.

[classroom-specific illustrations explaining the incentive structure]

[random assignment to either cognitive or social skills test]

Test - Cognitive Skill

In this test, you will see a series of images. Below is an example of the images you will solve. At the top of each image, there is a pattern with a piece that has been removed. Your task is to choose which of the six pieces completes the pattern correctly. For each image, there is only one correct piece. Look at the following example:

First, notice a square in the upper left, the upper right, and the lower left. Also, notice that the circle is eliminated when one moves from the upper left to the upper right. Finally, the rhombus is eliminated when moving from the upper left to the lower left. Therefore, the correct piece should eliminate the circle and the rhombus, leaving only a square. So, the correct answer is piece 5.

To give your answer to each image, you must choose the correct option and then continue to the next screen. After giving your answer you cannot go back.

You will have 5 minutes to complete the test, which consists of 18 images to solve. The percentage of correct answers will determine your chances of winning one of the 100.000 pesos bonuses if you are chosen for the drawing.

Are you ready?

Your 5 minutes will start as soon as you move to the next screen.

Problem 1

[screenshot of Raven's matrix]

[After participants submit an answer, a new matrix appears on the screen. The sequence of matrices is the same for all participants. Participants cannot return to a

previous screen. Participants do not have to provide answers for all 18 matrices.]

You have finished the test. You can proceed to the next screen.

How did you do on the test?

If we randomly choose 10 participants from this classroom, how many people do you think solved fewer correct problems than you?

[Slider from 0 to 10]

Test - Emotions

In this test, you will see a series of photographs. Below is an example of the pictures you will see. In each picture, you will see the eyes of a person. Below the picture, you will see four possible emotions that this person is feeling. Your task is to choose which of the four emotions correctly describes what the person is feeling. For each picture, there is only one emotion. Look at the following example:

[Happy, Disappointed, Shocked, Worried]

In this case, the correct answer is: Shocked.

To give your answer to each picture, you must choose the correct option and then continue to the next screen. After giving your answer you will not be able to go back.

You will have 5 minutes to complete the test, which consists of 36 photographs to solve. The percentage of correct answers you get will determine your chances of winning one of the 100.000 pesos bonuses if you are chosen for the drawing.

Are you ready?

Your 5 minutes will start as soon as you move to the next screen.

Photograph 1: Choose the word that best describes the photograph

[photo from Multiracial Reading the Mind in the Eyes Test]

[After participants submit an answer, a new photo appears on the screen. The sequence of photos is the same for all participants. Participants cannot return to a previous screen. Participants do not have to provide answers for all 36 photos.]

You have finished the test. You can proceed to the next screen.

How did you do on the test?

If we randomly choose 10 participants from this classroom, how many people do you think solved fewer correct photographs than you?

Part 2

At the beginning of this study, all participants took two tests, one on cognitive ability and one on emotions. In this part, we will ask you to recommend the people who in your opinion will score the best on each test.

You may recommend 3 people per test, but you may not recommend yourself.

We will allocate up to [classroom-specific number equal to 40% of class size] bonuses of 100.000 pesos for Part 2. The steps for allocating bonuses are explained below.

[random assignment to either quota or baseline condition]

[classroom-specific illustrations explaining the incentive structure depending on assign-

ment to either baseline or quota conditions]

[random assignment to either cognitive or social skills referral task]

Recommendation - Cognitive Skill

All participants took a test to identify the missing pattern in each image, as in the example below. This test is used to measure general intelligence.

Next, we will present you with a list of the names of all the students in this room. We will ask you to recommend the three people you think will score the highest on the general intelligence test.

If you are chosen by the computer, each of your recommendations in the top 3 increases your chances of winning one of the 100.000 pesos bonuses.

Select the students in this classroom who you consider to have the highest scores on the general intelligence test. (Select 3 students)

[Classroom-specific list of all classmate names visible on one screen. Participants have to pick 3 classmates to continue. Picking their own name invalidates their choices.]

Recommendation - Emotions

All participants took a test where they had to identify the emotion that best described the expression of each image as in the example below. This test is used to measure social skills.

Next, we will present you with a list of the names of all the students in this room. We will ask you to recommend 3 people you think will score the highest on the social skills test.

If you are chosen by the computer, each of your recommendations in the top 3 increases your chances of winning one of the 100.000 pesos bonuses.

Select the students in this classroom who you consider to have the highest scores on the social skills test. (Select 3 students)

[Classroom-specific list of all the names visible on one screen. Participants have to pick 3 classmates to continue. Picking their own name invalidates their choices.]

Part 3: Recommendation - Random draw

In this part, the computer will randomly choose three students who belong to strata 1, 2, or 3. We will ask you to nominate three people you think the computer will choose.

We will allocate up to [classroom-specific number equal to 20% of class size] bonuses of 100.000 pesos for Part 3. The steps for allocating the bonuses are explained below.

[classroom-specific illustrations explaining the incentive structure]

Figure A.7: Illustration for the Guessing Task

Select the students in this classroom who belong to strata 1, 2, or 3, who you think will be randomly selected by the computer (Select 3 students).

Part 4

Do you want to know your scores on the general intelligence test and the social skills test? We can analyze the data and give you a report that explains your strengths in these two areas. Also, what do these strengths mean, and how can you leverage them for your personal and professional development?

If you want to receive your skills report, we need to contact you again. We also want to be able to invite you to new studies where you can participate for more bonus money. Please indicate if you agree to be contacted again.

[I can be contacted for new studies and to send me my report. I can be contacted to

send my report, but not for new studies. No, I do not want to be contacted again.]

[if participant gives consent to be contacted again]
